The term "pharmaceutically acceptable salt" means either an acid addition salt or a basic addition salt which is compatible with the treatment of patients.

A "pharmaceutically acceptable acid addition salt" is any non-toxic organic or inorganic acid addition salt of the base compounds represented by Formulae I and II. Illustrative inorganic acids which form suitable salts include hydrochloric, hydrobromic, sulfuric and phosphoric acid and acid metal salts such as sodium monohydrogen

30

orthophosphate and potassium hydrogen sulfate. Illustrative organic acids which form suitable salts include the mono-, di- and tricarboxylic acids. Illustrative of such acids are, for example, acetic, glycolic, lactic, pyruvic, malonic, succinic, glutaric, fumaric, malic, tartaric, citric, ascorbic, maleic, hydroxymaleic, benzoic, hydroxybenzoic, phenylacetic, cinnamic, salicylic, 2-phenoxybenzoic, p-toluenesulfonic acid and other sulfonic acids such as methanesulfonic acid and 2-hydroxyethanesulfonic acid. Either the mono- or di-acid salts can be formed, and such salts can exist in either a hydrated, solvated or substantially anhydrous form. In general, the acid addition salts of a compound of Formula I or 2 are more soluble in water and various hydrophilic organic solvents, and generally demonstrate higher melting points in comparison to their free base forms. The selection criteria for the appropriate salt will be known to one skilled in the art. Other non-pharmaceutically acceptable salts, e.g. oxalates, may be used for example in the isolation of compounds of Formulae I and II for laboratory use, or for subsequent conversion to a pharmaceutically acceptable acid addition salt. It should be noted that compounds of Formulae I and II, wherein Z is N are not stable in the presence of strong acid (for example 1N HCl), therefore when preparing acid addition salts of such compounds, care must be taken to select an appropriately mild acid, for example citric acid.

A "pharmaceutically acceptable basic addition salt" is any non-toxic organic or inorganic base addition salt of the acid compounds represented by Formulae I and II. Illustrative inorganic bases which form suitable salts include lithium, sodium, potassium, calcium, magnesium or barium hydroxides. Illustrative organic bases which form suitable salts include aliphatic, alicyclic or aromatic organic amines such as methylamine, trimethylamine and picoline or ammonia. Those skilled in the art will appreciate that the selection of the appropriate salt may be important so that any ester functionality in the molecule is not hydrolyzed.

"Solvate" means a compound of Formula I or II or the pharmaceutically acceptable salt of a compound of Formula I or II wherein molecules of a suitable solvent are incorporated in a crystal lattice. A suitable solvent is physiologically tolerable at the dosage administered as the solvate. Examples of suitable solvents are

ethanol, water and the like. When water is the solvent, the molecule is referred to as a hydrate.

5 The term "stereoisomers" is a general term for all isomers of the individual molecules that differ only in the orientation of their atoms in space. It includes mirror image isomers (enantiomers), geometric (cis/trans) isomers and isomers of compounds with more than one chiral centre that are not mirror images of one another (diastereomers).

10 The term "treat" or "treating" means to alleviate symptoms, eliminate the causation of the symptoms either on a temporary or permanent basis, or to prevent or slow the appearance of symptoms of the named disorder or condition.

15 The term "therapeutically effective amount" means an amount of the compound which is effective in treating the named disorder or condition.

20 The term "pharmaceutically acceptable carrier" means a non-toxic solvent, dispersant, excipient, adjuvant or other material which is mixed with the active ingredient in order to permit the formation of a pharmaceutical composition, i.e., a dosage form capable of administration to the patient. One example of such a carrier is a pharmaceutically acceptable oil typically used for parenteral administration.

25 The term "schizophrenia" means schizophrenia, schizophreniform disorder, schizoaffective disorder and psychotic disorder wherein the term "psychotic" refers to delusions, prominent hallucinations, disorganized speech or disorganized or catatonic behavior. See Diagnostic and Statistical Manual of Mental Disorder, fourth edition, American Psychiatric Association, Washington, D.C.

30 The present invention includes within its scope prodrugs of the compounds of Formula I. In general, such prodrugs will be functional derivatives of the compounds of Formula I which are readily convertible *in vivo* into the required compound of Formula I. 30 The conversion of a given compound salt to a desired compound salt is achieved by applying standard techniques, in which an aqueous solution of the given salt is treated with

either a solution of a base e.g. sodium carbonate or potassium hydroxide, or an acid, e.g. HCl (caution when  $Z = N$ ), to liberate the neutral compound which is then extracted into an appropriate solvent, such as ether. The neutral compound is then separated from the aqueous portion, dried, and treated with the requisite acid or base to give the desired salt.

5

Also included within the scope of the invention are solvates of the invention. The formation of the solvate will vary depending on the compound and solvent used. In general, solvates are formed by dissolving the compound in the appropriate solvent and isolating the solvate by cooling or using an antisolvent. The solvate is typically dried or azeotroped under ambient conditions.

10

Prodrugs of compounds of Formula I may be conventional esters with available hydroxyl (or thiol) or carboxyl groups. For example, when one of  $R^1$ - $R^7$  is or contains a hydroxyl group in a compound of Formula I, it may be acylated using an activated acid in the presense of a base and, optionally, in inert solvent (e.g. an acid chloride in pyridine). Also, when one of  $R^1$ - $R^4$  is  $CO_2R^{10}$  in a compound of Formula I, wherein  $R^{10}$  is H, an ester may be formed by activation of the hydroxyl group of the acid and treatment with the appropriate alcohol in the presence of a base in an inert solvent. Some common esters which have been utilized as prodrugs are phenyl esters, aliphatic ( $C_1$ - $C_{24}$ ) esters, acyloxymethyl esters, carbamates and amino acid esters. Prodrugs of compounds of Formula I may also be formed by functional derivatization of substituents containing an acidic NH group, for example, compounds of Formula I, where one of  $R^1$ - $R^4$   $C(O)NR^8R^9$ ,  $SO_2NR^8R^9$ ,  $NHC(NR^{12})R^{11}$  or  $C(NR^{13})NR^{14}R^{15}$  and one of the groups attached to a nitrogen is H. Some common prodrugs for amides, imides and other NH-acidic compounds are N-Mannich bases, N-hydroxymethyl derivatives, N-acyloxyalkyl derivatives, and N-acyl derivatives.

In accordance with other aspects of the invention, the compounds of the present invention can be prepared by processes analogous to those established in the art. For example, as shown in Scheme 1, compounds of Formula I, wherein  $R^5$  is selected from  $SO_2Ar$ ,  $C(O)Ar$  and  $CH_2Ar$ , may be prepared by first treating compounds of Formula II, wherein  $R^1$ - $R^4$ ,  $R^5$  is H,  $R^6$ ,  $R^7$ , n, ----, X and Z are as defined in Formula I, with a

suitable base, followed by the addition of a reagent of either Formula B, C or D, wherein Ar is as defined in Formula I and Y is a suitable leaving group such as halo, arylsulfonyloxy or alkylsulfonyloxy, preferably bromo or chloro, to provide compounds of Formula I wherein R<sup>5</sup> is C(O)Ar, SO<sub>2</sub>Ar or CH<sub>2</sub>Ar, respectively. Therefore, for example, treatment of compounds of Formula A with a strong base such as lithium diisopropylamide, n-butyllithium or sodium bis(trimethylsilyl)amide in an inert solvent such as tetrahydrofuran or hexanes at a temperature in the range of -100 to 30 °C or, alternatively an organic amine in the presence of 4-dimethylaminopyridine (DMAP), in an inert solvent such as methylene chloride or chloroform, at a temperature in the range of 0-60 °C, followed by the addition of reagents of Formula B, C or D, provides compounds of Formula I, wherein R<sup>5</sup> is C(O)Ar, SO<sub>2</sub>Ar or CH<sub>2</sub>Ar respectively. Preferred conditions are sodium bis(trimethylsilyl)amide in tetrahydrofuran at temperatures in the range of 0 °C to room temperature or triethylamine and DMAP in methylene chloride at room temperature. Reagents B, C D are commercially available or can be prepared using standard methods known to those skilled in the art. The preparation of compounds of Formula II is described below.

Scheme 1

As shown in Scheme 2, compounds of Formula I wherein R<sup>5</sup> is Ar may be prepared by treating compounds of Formula II, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>5</sup> is H, R<sup>6</sup>, R<sup>7</sup>, n, ---, X and Z are as defined in Formula I, with an arylhalide of Formula E, wherein Ar is as defined in Formula I and Hal is selected from I, Br and Cl, under standard Ullmann

arylation conditions, for example in the presence of a base such as potassium carbonate and a catalyst such as copper, copper (I) iodide or copper (I) bromide or mixtures thereof, in an inert solvent such as

N-methylpyrrolidinone (NMP), dimethylformamide (DMF), hexamethylphosphoramide (HMPA) or dimethylsulfoxide (DMSO) at temperatures in the range of 150-200 °C. Preferred conditions are copper (I) bromide and copper in NMP at temperatures in the range of 160-170 °C.

Scheme 2

Compounds of Formula II are available by deprotecting compounds of Formula F, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup>, n, —, X and Z are as defined in Formula I and PG is a suitable protecting group, using standard deprotection conditions as shown in Scheme 3. When X is CR<sup>17</sup>, PG is preferably acetate which can be hydrolyzed under basic or acidic, preferably basic, conditions, for example sodium hydroxide in methanol at temperatures in the range of -20-100 °C, suitably -10-80 °C. When X is N, PG is preferably tosyl which can be removed under acidic conditions, for example HBr in acetic acid. It should be understood that the criteria for selection of a suitable protecting group would be known to a person skilled in the art as described in *Protective Groups in Organic Chemistry*, ed. McOmie, J.F.W. Plenum Press, 1973; and Greene, T.W. & Wuts, P.G.M., *Protective Groups in Organic Synthesis*, John Wiley & Sons, 1991.

Scheme 3

Compounds of Formula F, wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, X is  $CR^{17}$ , wherein  $R^{17}$  is as defined in Formula I, — is either a single or a double bond, Z is C or CH and PG is a suitable protecting group (Formulae F(a) and F(b)), may be prepared as shown in Scheme 4. A compound of Formula G, wherein  $R^1$ - $R^4$  are as defined in Formula I, may be condensed with a reagent of Formula H, wherein  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, either in acidic or basic conditions, in a suitable solvent at temperatures in the range of 25-100 °C, preferably, 60-90 °C, to provide compounds of Formula F(a) and F(a)' wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I. Suitable basic conditions include organic amines such as pyrrolidine or triethylamine in solvents such as methanol, ethanol and the like. Preferred basic conditions are pyrrolidine in ethanol at a refluxing temperature. Suitable acidic conditions include, for example, trifluoroacetic acid in acetic acid at a temperature in the range of 90-120 °C, preferably at around 110 °C. When the reaction of compound G with compound H is carried out in basic conditions, typically the regioisomer corresponding to F(a) is the sole product isolated. Under acidic conditions, both regioisomeric alkenes, F(a) and F(a)' may be isolated, the ratio of which will vary depending on reaction conditions and the identity and position of  $R^6$ . When  $R^6$  is H, this ratio is typically 1:1. Compounds of Formula F(a) and F(a)', wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, may be reduced using standard hydrogenation conditions or using metal hydride reducing reagents to provide compounds of Formula F(b) where  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, as shown in Scheme 4. Preferred is reduction by hydrogenation, using a suitable catalyst such as palladium or platinum on carbon in methanol or ethanol at room temperature. It should be noted that, in the series of reactions described above, the presence of the

protecting group PG, is not always necessary, therefore compounds of Formula II could be obtained directly from compounds of Formula G where PG is replaced with H.

Scheme 4

Compounds of Formula F, wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$ , and  $n$  are as defined in Formula I, ----- is either a single or a double bond, Z is C and X is N (Formulae F(c) and F(d)) may be prepared as shown in Scheme 5. A compound of Formula J, wherein  $R^1$ - $R^4$  are as defined in Formula I, PG is a suitable protecting group, such as tosylate, and Y is a leaving group such as halo, preferably chloro, can be reacted under standard palladium-catalyzed cross-coupling conditions with, for example, compounds of Formula K and K', wherein  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I and R is C-, alkyl, to provide compounds of Formula F(c) and F(c)', wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I. It will be appreciated that other metal coupling reagents could be used in place of the stannane, for example, boronic acid, chloro zinc and the like. Preferred coupling conditions include refluxing the indazole and heterocyclic metal reagent in an inert solvent such as dimethylformamide, tetrahydrofuran or toluene in the presence of tetrakis(triphenylphosphine) palladium (0). Compounds of Formula F(c) and F(c)', wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, may be reduced using standard hydrogenation conditions or using metal hydride reducing reagents as

described above to provide compounds of Formula F(d), wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I.

Scheme 5

- 5 Compounds of Formula F, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup> and n are as defined in Formula I, X is CR<sup>17</sup>, wherein R<sup>17</sup> is as defined in Formula I, Z is N and — is a single bond (Formula F(e)), may be prepared as shown in Scheme 6. A compound of Formula M or a compound of Formula N, wherein R<sup>1</sup>-R<sup>4</sup> are as defined in Formula I and PG is a suitable protecting group such as acetate or tosyl, may be reacted with a bicyclic
- 10 piperazine of Formula O, wherein R<sup>6</sup>, R<sup>7</sup> and n are as defined in Formula I, in the presence of a catalytic amount of an acid, such as p-toluenesulfonic acid or camphorsulfonic acid, in an inert solvent such as toluene or benzene, at temperatures

in the range of 25-120 °C, to provide compounds of Formula F(e), wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup> and n are as defined in Formula I and PG is a suitable protecting group. Preferred conditions are p-toluenesulfonic acid in toluene at a refluxing temperature.

Scheme 6

Compounds of Formula F, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup> and n are as defined in Formula I, Z and X are both N and — is a single bond (Formula F(f)), may be prepared as shown in Scheme 7. Compounds of Formula J, wherein R<sup>1</sup>-R<sup>4</sup> are as defined in Formula I, Y is a suitable leaving group such as halo, preferably chloro, and PG is an appropriate protecting group such as acetate or tosyl, preferably tosyl, may be reacted with a compound of Formula O, wherein R<sup>6</sup>, R<sup>7</sup> and n are as defined in Formula I, either neat or in an inert solvent at temperatures in the range of 25-150 °C. The reaction is preferably conducted neat at a temperature in the range of 100-130 °C.

Scheme 7

Compounds of Formula I, wherein X is CR<sup>17</sup>, wherein R<sup>17</sup> is selected from C<sub>1</sub>-alkyl and benzyl, may be prepared by treating compounds of Formula I or Formula F, wherein X is CR<sup>17</sup> and R<sup>16</sup> is H, with a strong base, such as n-butyllithium, in an inert solvent, such as tetrahydrofuran, at a temperature in the range of -100-0 °C (preferably -78 °C), followed by the addition of a reagent of formula R<sup>17</sup>-Y, wherein R<sup>17</sup> is selected from C<sub>1</sub>-alkyl and benzyl and Y is a suitable leaving group such as bromo, followed by warming to room temperature.

Compounds of Formula G, wherein R<sup>1</sup>-R<sup>4</sup> are as defined in Formula I and X is CR<sup>17</sup>, wherein R<sup>17</sup> is as defined in Formula I, are either commercially available or can be prepared using standard procedures. For example, compounds of Formula G may be prepared using the well known Fischer indolization method (see March, J, *Advanced Organic Chemistry*, John Wiley & Sons, 1985, p. 1032-1033, and references found therein) or using the procedure shown in Scheme 8. 4-Substituted anilines of Formula P, wherein R<sup>1</sup>-R<sup>4</sup> are as defined in Formula I, can be treated with reagents of Formula Q, wherein X is CR<sup>17</sup> and R<sup>17</sup> is as defined in Formula I, in the presence of a base such as sodium bicarbonate or potassium carbonate in an alcoholic solvent at temperatures in the range of 60-100 °C, to provide intermediates of Formula S. Preferred conditions are sodium bicarbonate in ethanol at around 80 °C. Intermediates of Formula S can be cyclized in the presence of reagents of Formula T, wherein R is, for example, methyl or trifluoromethyl (which is preferred) at temperatures in the range of 60-100 °C, to provide indoles of Formula U. The preferred conditions are trifluoroacetic anhydride

and trifluoroacetic acid at refluxing temperatures. Finally, compounds of Formula U can be treated under standard deprotection conditions, for example alkali hydroxides in an alcoholic solvent, to provide indoles of Formula G, wherein  $R^1$ - $R^4$  are as defined in Formula I and  $X$  is  $CR^{17}$  wherein  $R^{17}$  is as defined in Formula I. Preferred conditions for this reaction are potassium hydroxide in ethanol at room temperature. The reagents of Formula P and Q, are either commercially available or can be prepared using processes analogous to those established in the art.

Scheme 8

Compounds of Formula J, wherein  $R^1$ - $R^4$  are as defined in Formula I, Y is a suitable leaving group and PG is a suitable protecting group can be prepared from the corresponding unprotected compound V using standard protecting group procedures as shown below in Scheme 9. For example, the introduction of the tosyl group is conveniently performed using tosyl chloride in the presence of a base such as triethylamine in an inert solvent such as methylene chloride at temperatures in the range of 0-60 °C, preferably room temperature.

Scheme 9

Compounds of Formula V wherein R<sup>1</sup>-R<sup>4</sup> are as defined in Formula I and Y is a suitable leaving group are either commercially available or can be prepared using standard indazole synthesis procedures as described in *Organic Synthesis*, ed. Horning, E.C. John Wiley & Sons, 1955, vol. 3, p. 475-479; or Baker, R. *et al.* EP 494,774.

An alternative procedure for the preparation of compounds of Formula I, wherein X is N, is shown in Scheme 10 and is analogous to the procedure described in detail in Baker, R. *et al.* EP 494,774. Compounds of Formula W, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup>, n, ----- and Z are as defined in Formula I and D is a readily displaceable group, such as a C<sub>1</sub>-alkanoxy group (suitably acetoxy) or an arylsulfoxy group (suitably tosyl), can be cyclized in a suitable organic solvent at an elevated temperature, for example a mixture of xylene and

2,6-lutidine at around 140 °C, or in a melt, which requires a temperature of around 170 °C, to provide compounds of Formula X, wherein R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>, R<sup>7</sup>, n, ----- and Z are as defined in Formula I. The compounds of Formula I are thus available from compounds of Formula X by reaction with either a reagent of Formula B, C, D or E using the procedures described previously.

Scheme 10

When D is acetoxy, compounds of Formula W, wherein  $\text{R}^1$ - $\text{R}^4$ ,  $\text{R}^6$ ,  $\text{R}^7$ ,  $n$ , ----- and Z are as defined in Formula I, may be prepared by treating the corresponding carbonyl compounds of Formula Y, wherein  $\text{R}^1$ - $\text{R}^4$ ,  $\text{R}^6$ ,  $\text{R}^7$ ,  $n$ , ----- and Z are as defined in Formula I, or a protected derivative thereof, with hydroxylamine hydrochloride, advantageously in pyridine at a refluxing temperature, followed by acylation with acetic anhydride, suitably in the presence of 4-dimethylaminopyridine in methylene chloride at room temperature, as shown in Scheme

Scheme 11

As shown in Scheme 12, the N-formyl protected derivative of compounds of Formula Y, wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$ ,  $n$ ,  $Z$  and ----- are as defined in Formula I, may be prepared by oxonolysis of an indole of Formula AA, wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$ ,  $n$ ,  $Z$  and ----- are as defined in Formula I and X is CH, (available from, for example, compounds of Formula F, wherein  $R^1$ - $R^4$ ,  $R^6$ ,  $R^7$ ,  $n$ ,  $Z$  and ----- are as defined in Formula I and X is CH, by removal of the protecting group) followed by reductive workup, preferably using dimethylsulfide.

Scheme 12

The bicyclic piperidinones H and piperazines O, wherein  $R^6$ ,  $R^7$  and  $n$  are as defined in Formula I, are either commercially available or can be prepared using procedures known in the art. For example, bicyclic piperidinones of Formula H may be prepared according to procedures described in King, F. D., J. Chem. Soc. Perkin Trans. I, 1986:447-453 and bicyclic piperazines of Formula O may be prepared according to procedures described in Power, P. *et al.*, US 5,576,314; Saleh, M. A. *et al.* J. Org. Chem. 58, 1993:690-695; Urban, F. J. Heterocyclic Chem. 32, 1995:857-861; Bright, G. *et al.* WO 90/08148; de Costa, B. R. *et al.* J. Med. Chem. 36, 1993:2311-2320; and Botre, C. *et al.* J. Med. Chem. 29, 1986:1814-1820. The bicyclic piperidine K may be prepared from piperidinone H using standard chemistries, for example, by reacting the ketone with a base, such as lithium diisopropylamide or triethylamine, and a suitable triflating agent, such as N-phenyltriflimide or triflic anhydride, and converting the resulting triflate to a compound of Formula K by treatment with, for example, a palladium catalyst and a

bis(trialkyltin). Alternatively, bicyclic piperidine K may be prepared by forming the tosylhydrazone of a compound of Formula H and using standard Shapiro conditions, trap the vinyl anion with a suitable reagent like tributyltin chloride.

It should be noted that one skilled in the art would realize that the sequence of reactions described above for the preparation of compounds of Formula I can be varied. For example, the R<sup>5</sup> group may be incorporated into the molecule before the addition of the group at the indole or indazole

3-position. Further, a compound of Formula I may be converted to another compound of Formula I using known chemistries, for example alkylation, arylation, oxidation/reduction and acylation to obtain the desired substitution at R<sup>1</sup> to R<sup>4</sup>.

In some cases, the chemistries outlined above may have to be modified, for instance by use of protecting groups, to prevent side reactions due to reactive groups, such as reactive groups attached as substituents. This may be achieved by means of conventional protecting groups, as described in *Protective Groups in Organic Chemistry*, ed. McOmie, J.F.W. Plenum Press, 1973; and Greene, T.W. & Wuts, P.G.M., *Protective Groups in Organic Synthesis*, John Wiley & Sons, 1991.

In another of its aspects, the present invention provides compounds, useful as intermediates in the preparation of compounds of Formula I and having the general Formula II:

wherein R<sup>5</sup> is H and R<sup>1</sup>-R<sup>4</sup>, R<sup>6</sup>-R<sup>7</sup>, X, Z, n and — are as defined in Formula I (and a

salt, solvate or hydrate thereof) and where embodiments of the Formula II compounds are as described above for Formula I compounds (excepting R<sup>5</sup>).

Specific compounds of Formula II include:

5,7-Difluoro-3-[(7R or 7S)(8a-R,S)-octahydro-7-indoliziny]-1H-indole, Isomer II.

20 In a further aspect of the present invention, compounds of Formula I, specifically compounds of Formula I wherein R<sup>5</sup> is selected from CH<sub>2</sub>Ar, SO<sub>2</sub>Ar and C(O)Ar, are useful as intermediates in the preparation of compounds of Formula II, which may be used as antimigraine agents as described in a co-pending application filed on an even  
25 date herewith and the contents of which are incorporated herein by reference.

In another embodiment of the invention, compounds of Formula I can be used to distinguish 5-HT<sub>6</sub> receptors from other receptor subtypes, for example glutamate or opioid  
30 receptors, within a population of receptors, and in particular to distinguish between the 5-HT<sub>6</sub> and other 5-HT receptor subtypes. The latter can be achieved by incubating preparations of the 5-HT<sub>6</sub> receptor and one of the other 5-HT receptor subtypes (for example 5-HT<sub>2A</sub>) with a 5-HT<sub>6</sub>-selective compound of the invention and then incubating the

resulting preparation with a radiolabeled serotonin receptor ligand, for example [ $^3\text{H}$ ]-serotonin. The 5-HT<sub>6</sub> receptors are then distinguished by determining the difference in membrane-bound activity, with the 5-HT<sub>6</sub> receptor exhibiting lesser radioactivity, i.e., lesser [ $^3\text{H}$ ]-serotonin binding, than the other 5-HT receptor subtype.

5

In another embodiment of the invention, a compound of Formula I is provided in labeled form, such as radiolabeled form, e. g. labeled by incorporation within its structure  $^3\text{H}$  or  $^{14}\text{C}$  or by conjugation to  $^{125}\text{I}$ . In another aspect of the invention, the compounds in labeled form can be used to identify 5-HT<sub>6</sub> receptor ligands by techniques common in the art. This can be achieved by incubating the receptor or tissue in the presence of a ligand candidate and then incubating the resulting preparation with an equimolar amount of radiolabeled compound of the invention such as

10

[ $^{125}\text{I}$ ]-1-(4-iodophenylsulfonyl)-5-fluoro-3-[(8a-R,S)-1,2,3,5,8,8a-hexahydro-7-

15

indoliziny]indole. 5-HT<sub>6</sub> receptor ligands are thus revealed as those that are not significantly displaced by the radiolabeled compound of the present invention. Alternatively, 5-HT<sub>6</sub> receptor ligand candidates may be identified by first incubating a radiolabeled form of a compound of the invention then incubating the resulting preparation in the presence of the candidate ligand. A more potent 5-HT<sub>6</sub> receptor ligand will, at equimolar concentration, displace the radiolabeled compound of the invention.

20

A radiolabelled compound of Formula I may be prepared using standard methods known in the art. For example a compound of Formula I wherein one of R<sup>1</sup>-R<sup>4</sup> is radioactive iodo or Ar is substituted with a radioactive iodo group may be prepared from the corresponding trialkyltin (suitably trimethyltin) derivative using standard iodination conditions, such as [ $^{125}\text{I}$ ] sodium iodide in the presence of chloramine-T in a suitable solvent, such as dimethylformamide. The trialkyltin compound may be prepared from the corresponding non-radioactive halo, suitably iodo, compound using standard palladium-catalyzed stannylation conditions, for example hexamethylditin in the presence of tetrakis(triphenylphosphine) palladium (0) in an inert solvent, such as dioxane, and at elevated temperatures, suitably 50-100 °C. Alternatively, tritium may

30

be incorporated into a compound of Formula I using standard techniques, for example by hydrogenation of a suitable precursor to a compound of Formula I using tritium gas and a catalyst.

5           Compounds of Formula I are useful as pharmaceuticals for the treatment of various conditions in which the use of a 5-HT<sub>6</sub> antagonist is indicated, such as psychosis, schizophrenia, manic depression, depression, neurological disturbances, memory disturbances, Parkinsonism, amyotrophic lateral sclerosis, Alzheimer's disease and Huntington's disease. In another of its aspects, the present invention  
10 provides pharmaceutical compositions useful to treat 5-HT<sub>6</sub>-related medical conditions, in which a compound of Formula I is present in an amount effective to antagonize 5-HT<sub>6</sub> receptor stimulation, together with a pharmaceutically acceptable carrier. In a related aspect, the invention provides a method for treating medical conditions for which a 5-HT<sub>6</sub> receptor antagonist is indicated, which comprises the step of  
15 administering to the patient an amount of a compound of Formula I effective to antagonize 5-HT<sub>6</sub> receptor stimulation, and a pharmaceutically acceptable carrier therefor.

For use in medicine, the compounds of the present invention can be administered in  
20 a standard pharmaceutical composition. The present invention therefore provides, in a further aspect, pharmaceutical compositions comprising a pharmaceutically acceptable carrier and a Formula I compound or a pharmaceutically acceptable salt, solvate or hydrate thereof, in an amount effective to treat the target indication.

25           The compounds of the present invention may be administered by any convenient route, for example by oral, parenteral, buccal, sublingual, nasal, rectal, patch, pump or transdermal administration and the pharmaceutical compositions formulated accordingly.

Compounds of Formula I and their pharmaceutically acceptable salts which are  
30 active when given orally can be formulated as liquids, for example syrups, suspensions or emulsions, or as solid forms such as tablets, capsules and lozenges. A liquid formulation will generally consist of a suspension or solution of the compound or pharmaceutically

acceptable salt in a suitable pharmaceutical liquid carrier for example, ethanol, glycerine, non-aqueous solvent, for example polyethylene glycol, oils, or water with a suspending agent, preservative, flavouring or colouring agent. A composition in the form of a tablet can be prepared using any suitable pharmaceutical carrier routinely used for preparing solid formulations. Examples of such carriers include magnesium stearate, starch, lactose, sucrose and cellulose. A composition in the form of a capsule can be prepared using routine encapsulation procedures. For example, pellets containing the active ingredient can be prepared using standard carriers and then filled into a hard gelatin capsule; alternatively, a dispersion or suspension can be prepared using any suitable pharmaceutical carrier, for example aqueous gums, celluloses, silicates or oils and the dispersion or suspension filled into a soft gelatin capsule.

Typical parenteral compositions consist of a solution or suspension of the compound or pharmaceutically acceptable salt in a sterile aqueous carrier or parenterally acceptable oil, for example polyethylene glycol, polyvinyl pyrrolidone, lecithin, arachis oil or sesame oil. Alternatively, the solution can be lyophilized and then reconstituted with a suitable solvent just prior to administration.

Compositions for nasal administration may conveniently be formulated as aerosols, drops, gels and powders. Aerosol formulations typically comprise a solution or fine suspension of the active substance in a physiologically acceptable aqueous or non-aqueous solvent and are usually presented in single or multidose quantities in sterile form in a sealed container, which can take the form of a cartridge or refill for use with an atomising device. Alternatively, the sealed container may be a unitary dispensing device such as a single dose nasal inhaler or an aerosol dispenser fitted with a metering valve which is intended for disposal after use. Where the dosage form comprises an aerosol dispenser, it will contain a propellant which can be a compressed gas such as compressed air or an organic propellant such as fluorochlorohydrocarbon. The aerosol dosage forms can also take the form of a pump-atomizer.

Compositions suitable for buccal or sublingual administration include tablets, lozenges, and pastilles, wherein the active ingredient is formulated with a carrier such as

sugar, acacia, tragacanth, or gelatin and glycerine. Compositions for rectal administration are conveniently in the form of suppositories containing a conventional suppository base such as cocoa butter.

Preferably, the composition is in unit dose form such as a tablet, capsule or ampoule. Suitable unit dosages, i.e. therapeutically effective amounts, can be determined during clinical trials designed appropriately for each of the conditions for which administration of a chosen compound is indicated and will of course vary depending on the desired clinical endpoint. Each dosage unit for oral administration may contain from 0.01 to 500 mg/kg (and for parenteral administration may contain from 0.1 to 50 mg) of a compound of Formula I, or a pharmaceutically acceptable salt thereof calculated as the free base, and will be administered in a frequency appropriate for initial and maintenance treatments. For laboratory use, the present compounds can be stored in packaged form for reconstitution and use.

#### Example 11: Binding Affinity for the 5-HT<sub>6</sub> Receptor

5

All of the compounds of the invention were evaluated using cell types receptive specifically to the 5-HT<sub>6</sub> receptor (for cloning and characterization of the human 5-HT<sub>6</sub> receptor see Kohen, *et al.* J. Neurochemistry, 66, 1996: 47-56). The assay protocol generally entailed the incubation of membranes prepared from cells expressing the 5-HT<sub>6</sub> receptor with <sup>3</sup>H-LSD (2 nM). Increasing levels of the test compound were incubated with the radioligand and the membrane homogenates prepared from the recombinant cells. After a 60 minute incubation at 37 °C, the incubation was terminated by vacuum filtration. The filters were washed with buffer and the filters were counted for radioactivity using liquid scintillation spectrometry. The affinity of the test compound for the 5-HT<sub>6</sub> receptor was determined by computer-assisted analysis of the data and determining the amount of the compound necessary to inhibit 50% of the binding of the radioligand to the receptor. Concentrations ranging from 10<sup>-11</sup> M to 10<sup>-5</sup> M of the test

10

15

compound were evaluated. For comparison, the affinity of clozapine ( $K_i = 3 \text{ nM}$ ) for the 5-HT<sub>6</sub> receptor was used as a standard. Affinity for the 5-HT<sub>6</sub> receptor is expressed as the amount (in percent) of binding of the radioligand that is inhibited in the presence of 100 nM of test compound. A greater percent inhibition indicates greater affinity for the 5-HT<sub>6</sub> receptor. Selected compounds of the invention showed an percent inhibition of greater than 50% for the 5-HT<sub>6</sub> receptor. Specific compounds of the invention, for example, those of examples 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k, 6l, 6m, 6n, 6p, 6u, 6v, 6x, 6y, 6z, 6aa, 6bb, 6cc, 6dd, 6ee, 6gg, 6hh, 6ii, 6jj, 6kk, 6ll, 6mm, 6nn, 6oo, 6pp, 6qq, 6rr, 6ss, 6tt, 6jj, 6kk, 7a, 7b, 9a, 10a, 10b, 10c, 10d, 10e, 10f, 10h, 10i, 10j and 10k, showed an percent inhibition of greater than 80% for the 5-HT<sub>6</sub> receptor. More specific compounds of the invention, for example, those of examples 6a, 6b, 6c, 6d, 6e, 6f, 6g, 6h, 6i, 6j, 6k, 6l, 6m, 6v, 6x, 6y, 6z, 6aa, 6bb, 6cc, 6dd, 6ii, 6jj, 6kk, 6mm, 6nn, 6oo, 6pp, 6qq, 6rr, 6jj, 6kk, 7a, 9a, 10e, 10f and 10i, showed an percent inhibition of greater than 95% for the 5-HT<sub>6</sub> receptor. In terms of selectivity, selected compounds of the invention showed an percent inhibition of greater than 50% for the 5-HT<sub>6</sub> receptor and also had an percent inhibition less than 50% for other serotonin receptors, specifically the 5-HT<sub>2A</sub>, 5HT<sub>2C</sub> and 5-HT<sub>7</sub> receptors. Specific compounds, for example those of examples 6a, 6b, 6c, 6d, 6g, 6j, 6l, 6m, 6n, 6p, 6u, 6x, 6y, 6z, 6aa, 6bb, 6cc, 6dd, 6ee, 6gg, 6hh, 6ii, 6ll, 6mm, 6nn, 6oo, 6pp, 6qq, 6rr, 6ss, 6tt, 6jj, 6kk, 10f and 10b showed an percent inhibition of greater than 80% for the 5-HT<sub>6</sub> receptor and less than 20% for the 5-HT<sub>2A</sub>, 5HT<sub>2C</sub> and 5-HT<sub>7</sub> receptors. More specific compounds, for example those of examples 6m, 6x, 6z, 6ll, 6mm, 6nn, 6oo, 6pp, 6qq, 6rr, 6jj and 10b showed an percent inhibition of greater than 90% for the 5-HT<sub>6</sub> receptor and less than 10% for the 5-HT<sub>2A</sub>, 5HT<sub>2C</sub> and 5-HT<sub>7</sub> receptors

## Example 12: Functional Assay

The 5HT<sub>6</sub> receptor responds to serotonin and other agonists by increasing adenylyl cyclase mediated production of cyclic AMP. Particular test compounds were assayed for their effect on adenylyl cyclase activity using the procedure described below.

Compounds acting as antagonists at the 5HT<sub>6</sub> receptor will antagonize the agonist effect of serotonin and thus, will block the serotonin-induced increase in adenylyl cyclase activity.

HEK 293 cells stably expressing the human 5HT<sub>6</sub> receptor were plated in 6 well plates in DMEM (Dulbecco's Modified Eagle Medium)/F12 (Nutrient Mixture F12 – Ham) media with 10% FCS (fetal calf serum) and G418 (Geneticin Disulfate, 500ug/ml), and incubated at 37 °C in a CO<sub>2</sub> incubator. The cells were allowed to grow to about 70% confluence before use in the assay.

The culture medium of each well was removed, and the wells were washed once with serum free media. Then 2 ml of SFM+IBMX medium (SFM with 0.5 mM IBMX, 3-isobutyl-1-methylxanthine, 0.1% ascorbic acid and 10 mM pargyline) was added to each well and the wells were incubated at 37 °C for 10 min. Following incubation, the SFM+IBMX medium was removed from each well and fresh SFM+IBMX media was added to the wells separately with one of a) serotonin (1 µM final concentration); b) test compound (100 nM and 10 µM, to test for agonist activity); and c) test compound (100 nM and 10 µM) along with serotonin (µM final concentration, to test for antagonist activity). Basal adenylyl cyclase activity was determined from wells with only SFM+IBMX media added.

The cells were then incubated at 37 °C for 30 minutes in a CO<sub>2</sub> incubator. Following incubation, the media were removed from each well. The wells were washed once with 1 ml of PBS (phosphate buffered saline). Each well was then treated with 1 mL cold 95% ethanol:5mM EDTA (2:1) at 4 °C for 1 hour. The cells from each well were then scraped and transferred into individual Eppendorf tubes. The tubes were centrifuged

for 5 minutes at 4 °C, and the supernatants were transferred to new Eppendorf tubes and stored at 4 °C. The pellets were discarded and the supernatants were stored at 4 °C until assayed for cAMP concentration. cAMP content for each extract was determined in duplicate by EIA (enzyme-immunoassay) using the Amersham Biotrak cAMP EIA kit (Amersham RPN 225). Final results were expressed as %basal response for agonists and % reversal of serotonin response for antagonists.

The total stimulation of adenylyl cyclase by serotonin ( $S_o$ ) was determined as the difference in concentration of cAMP in the serotonin-treated cells ( $C_d$ ) and the basal-treated cells ( $C_i$ ).

$$S_o = C_i - C_d$$

The net stimulation ( $S$ ) of basal adenylyl cyclase by an agonist test compound was determined as the difference in cAMP concentration in the drug-treated cell ( $C$ ) and the basal-treated cells ( $C_i$ ).

$$S = C_i - C$$

The net stimulation ( $S_s$ ) of basal adenylyl cyclase by serotonin in the presence of an antagonist test compound was determined as the difference in cAMP concentration in the serotonin-drug-treated cells ( $C_s$ ) and the basal-treated cells ( $C_i$ ).

$$S_s = C_i - C_s$$

The ability of the antagonist test compound to reverse the serotonin stimulation of adenylyl cyclase activity (% reversal, %R) was determined by the formula:

$$\%R = (1 - S_s/S_o) \times 100$$

Selected compounds of the invention, for example those of Examples 6x, 6y, 10c, 10e, 10a, 10d, 10f, 10b, 6b and 6j, were able to reverse the serotonin stimulation of adenylyl

cyclase and thus were shown to behave as a 5-HT<sub>6</sub> receptor antagonist.
